ABSTRACT
Black bear parathyroid hormone (PTH) and functional fragments thereof are provided. Also provided are methods of using black bear PTH and functional fragments for increasing cAMP in a bone-forming cell; reducing apoptosis in a bone-forming cell; decreasing the ratio of expression levels of Bax protein to Bcl-2 protein in a bone-forming cell; increasing the expression level of one or more of a bone matrix protein, a transcriptional activator, or a transcriptional regulator in a bone-forming cell; enhancing bone mineral density; increasing bone mass; decreasing bone loss; or reducing the incidence of bone fractures, or any combination thereof, in a subject; also provided are antibodies directed against black bear parathyroid hormone (PTH) and functional fragments thereof.

METHODS OF USING BLACK BEAR PARATHYROID HORMONE

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application No. 60/736,145, filed Nov. 10, 2005, which is incorporated herein by reference in its entirety.

STATEMENT REGARDING FEDERALLY-SPONSORED RESEARCH

This invention was made with United States government support awarded by the National Institutes of Health (NIAMS AR050420 and NIA R21AA 14399-01A2) and the National Science Foundation (IBN-0343515). The United States government has certain rights in this invention.

BACKGROUND

Bone loss diseases are currently a health threat for approximately 44 million Americans, including 10 million with osteoporosis and 34 million with low bone mass and at risk for developing osteoporosis. The number of Americans with osteoporosis is expected to rise by 2020. Consequently, a large number of individuals are at risk for bone fracture due to low bone mass. Approximately 40% of white women and 13% of white men over age 50 are at risk for hip, spine, or forearm fracture within their lifetime. The costs associated with osteoporosis-related fractures were approximately $18 billion dollars in 2002, and are expected to continue climbing. In addition to primary (age-related) osteoporosis, disuse osteoporosis is an important clinical problem, especially for patients chronically immobilized due to stroke or spinal cord injury. Fracture rates double compared to healthy controls in the first year following spinal cord injury and are also elevated compared to healthy controls after the onset of stroke. Disuse increases fracture rates primarily because reduced skeletal loading causes unbalanced bone remodeling which leads to bone loss.

SUMMARY

In one embodiment, the invention provides an isolated polypeptide comprising at least 10 consecutive amino acid residues of SEQ ID NO: 2 wherein the polypeptide comprises at least one of amino acid residues 41 and 52 of SEQ ID NO: 2. The present invention also provides an isolated polynucleotide comprising SEQ ID NO: 1.

In another embodiment, the invention provides a method of increasing cAMP levels in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide increases cAMP levels in the bone-forming cell.

In yet another embodiment, the invention provides a method of reducing apoptosis in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide reduces apoptosis in the bone-forming cell.

In still another embodiment, the invention provides a method of decreasing the ratio of expression levels of Bax protein to Bcl-2 protein in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide decreases the ratio of expression levels of Bax protein to Bcl-2 protein in the bone-forming cell.

In yet another embodiment, the invention provides a method of increasing the expression level of a bone matrix protein, a transcriptional activator, or a transcriptional regulator in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide increases the expression level of the bone matrix protein, the transcriptional activator, or the transcriptional regulator in the bone-forming cell.

In still another embodiment, the invention provides a method of enhancing bone mineral density, increasing bone mass, decreasing bone loss, or reducing the incidence of bone fractures in a subject, comprising contacting a bone-forming cell in the subject with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide enhances bone mineral density, increases bone mass, decreases bone loss, or reduces the incidence of bone fractures in the subject.

In yet another embodiment, the invention provides a method of enhancing bone mineral density, increasing bone mass, decreasing bone loss, or reducing the incidence of bone fractures, or any combination thereof, in a subject, comprising contacting a bone-forming cell in the subject with an effective amount of a polypeptide comprising bone parathyroid hormone or a functional fragment thereof, wherein contacting the bone-forming cell with the polypeptide enhances bone mineral density, increases bone mass, decreases bone loss, or reduces the incidence of bone fractures in the subject.

In still another embodiment, the invention provides an isolated polypeptide consisting essentially of amino acid residues 1-34 of SEQ ID NO: 2.

In yet another embodiment, the invention provides an isolated polypeptide consisting essentially of amino acid residues 1-36 of SEQ ID NO: 2.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows ultimate stress, a measure of bone strength, and ash fraction, a measure of bone mineral content, which both increase with age in black bears.

FIG. 2 shows that serum osteocalcin levels are positively correlated with serum parathyroid hormone (PTH) levels (p=0.0007, n=27) in black bears for pooled pre-hibernation, hibernation, and post-hibernation samples.

FIG. 3 shows normalized serum resorption (ICTP) and formation (PICP and osteocalcin) marker concentrations during the 3 month disuse period.

FIG. 4 shows that the amount of PGE2 released by osteoblastic cells was greatest when the cells were treated with serum collected in the post-hibernation period.

FIG. 5 shows the sequence of the mature black bear PTH protein (SEQ ID NO: 2) compared to other known PTH sequences, including monkey (SEQ ID NO: 5), human (SEQ ID NO: 6), horse (SEQ ID NO: 7), dog (SEQ ID NO: 8), cat (SEQ ID NO: 9), bovine (SEQ ID NO: 10), pig (SEQ ID NO: 11), rat (SEQ ID NO: 12), and mouse (SEQ ID NO: 13).

FIG. 6 shows that both human and black bear PTH 1-34 upregulate osteocalcin (n=2).
FIG. 7 shows the effects of human and black bear PTH 1-34 on osteocalcin mRNA expression (n-4).

DETAILED DESCRIPTION

In humans and most other mammals, factors such as aging and extended periods of disuse can lead to osteoporosis and an increased risk of fracture. Disuse due to spinal cord lesion significantly decreases bone mineral density, particularly in the tibia and femur, and significantly reduces the cross-sectional moment of inertia of the femoral diaphysis. Thus, bone bending strength is reduced by spinal cord injury and fracture risk is increased. Disuse due to stroke also increases fracture risk. In addition, mechanical unloading of bone can cause rapid bone loss due to immediate increases in bone resorption in addition to sustained decreases in bone formation. Disuse-induced changes in bone remodeling increase intracortical porosity, and reduce the cross-sectional and mechanical properties of long bone diaphyses. Unloading also considerably reduces trabecular bone mass and microarchitecture.

The deleterious effects of disuse on bone may continue into the remobilization period. Some bone may be recovered during remobilization, but recovery is slow and often incomplete. For example, the rate of bone loss during bedrest is more than three times greater than the rate of bone gain during remobilization, and the recovery of bone lost in spaceflight can be incomplete even after 5 years. When disuse-induced changes in bone can be completely reversed by resumed activity, the remobilization period is often 2 to 3 times longer than the immobilization period. Bone formation decreases and/or bone resorption increases in many situations that reduce mechanical loads on bone. However, both resorption and formation increase during canine forelimb immobilization, yet there is significant bone loss in that case. Likewise, thigh bone turnover occurs in patients with spinal cord injury, which leads to bone loss and increased fracture incidence.

In contrast to this, black bears do not suffer significant bone loss due to aging (FIG. 1) or, more importantly, the extended periods of disuse that occur during hibernation. Hibernating black bears have immobilization and active periods that can be approximately equal in length in northern regions. Data on serum markers of bone metabolism (see below) suggest that both resorption and formation increase during disuse in bears, with a normal lag time (i.e., reversal period) between resorption and formation, and that the increase in formation remains coupled and balanced with the increase in resorption. Histological data from black bear iliac crest biopsies also show increased resorption and formation during inactivity. However, bears are unique in that trabecular bone volume, bone mineral density, and bone mineral content do not decrease during hibernation. Moreover, cortical bone strength and ash fraction increase with age, and porosity does not change with age in black bears, despite annual periods of disuse. Cortical bone porosity is significantly lower in hibernating grizzly bears than in active grizzly bears, and femoral cross-sectional geometry and strength are unaffected by hibernation.

Bears have evolved many unique biological mechanisms to survive long periods of immobilization without food. These mechanisms appear to include the recycling of calcium and other products of bone catabolism, since bears increase bone turnover but do not excrete waste during hibernation. In humans, bedrest-induced disuse osteoporosis is caused primarily by increased resorption without a corresponding increase in formation. This results in hypercalcemia and a negative calcium balance brought about by increased urinary and fecal calcium. Since bears do not urinate or defecate during hibernation, it is likely that most of the calcium released from bone by resorption is recycled back into bone via osteoblastic bone formation. Ionized calcium is found to increase by about 23% during hibernation, possibly because of the lag time between resorption and formation. Paradoxically, black bear PTH levels are highest when levels of ionized calcium are highest (Table 1). Taken together, these findings suggest that bears have evolved biological mechanisms to avoid osteoporosis.

The mechanisms that uncouple bone formation from resorption during disuse in most animals are unknown, but likely involve both mechanical and biochemical factors. Lack of mechanical strain may lead to increased resorption by initiating osteocyte apoptosis and concomitantly reducing osteoblastic activity. Hormones such as human PTH can sensitize bone cells to mechanical stimulation and synergistically, with mechanical loading, increase bone formation. Human PTH given once daily to humans increases bone mass and decreases fracture incidence. Thus, in black bears, circulating PTH may sensitize bone cells to low levels of mechanical stimulation (possibly due to shivering or repositioning in the hibernaculum) to help maintain bone formation during disuse. PTH may also help maintain bone formation in black bears by stimulating osteoblast differentiation and inhibiting osteoblast apoptosis.

PTH is the primary regulator of blood calcium levels, and thus plays a role in maintaining homeostatic serum calcium levels in black bears during disuse. Serum PTH levels are positively correlated with the bone formation marker osteocalcin in active and hibernating black bears (FIG. 2), and both osteocalcin and PTH increase during hibernation. In addition, black bear PTH concentration is highest when ionized calcium concentration is highest. Since bone resorption increases during hibernation but total serum calcium (tCa) remains unchanged, increased levels of PTH likely cause increased renal reabsorption of calcium, facilitating the recycling of mineral back into the bone with a balanced increase in bone formation. This leads to the observed preservation of trabecular and cortical bone properties like bone mineral density (“BMD”) and cortical porosity. Bone resorption increases during hibernation, but blood calcium concentration remains constant despite the fact that bears do not excrete waste during hibernation. The calcium liberated by bone resorption during hibernation may be recycled and put back into bone by maintaining balanced coupling of bone formation with bone resorption. This supports the idea that PTH has anabolic effects in hibernating black bears and provides an explanation for the bears’ distinctive ability to maintain balanced bone remodeling during hibernation. The anabolic effects of PTH may be enhanced in black bears when physical activity is resumed following arousal from hibernation. Mechanical loading and human PTH have previously been shown to act synergistically to increase bone formation in vivo in rats and biochemical signaling in vitro. During remobilization in the spring, bone formation in black bears, as indicated by serum osteocalcin, remains higher than prehibernation levels.

The sequence for the polynucleotide which encodes black bear (Ursus americanus) parathyroid hormone (PTH) (SEQ ID NO: 1) was discovered as well as the polypeptide sequence for the mature 84 amino acid PTH protein (SEQ ID NO: 2). In addition, the mRNA (SEQ ID NO: 3) which encodes the full length PTH protein (SEQ ID NO: 4), including a 25 amino acid signal peptide (amino acid residues 1-25 of SEQ ID NO: 4) and a 6 amino acid propeptide (amino acid residues 26-31 of SEQ ID NO: 4) has been sequenced. The mature black bear PTH protein differs from other known PTH proteins (FIG. 5).
Compared to human PTH, black bear PTH has 11 different amino acid residues out of a total of the 84 amino acid residues of the full-length, mature PTH polypeptide. Also described herein are various methods of use for black bear PTH and functional fragments thereof. It is specifically envisioned that polypeptide subfragments comprising at least 10 consecutive amino acid residues of SEQ ID NO: 2 and including at least one of amino acid residues 41 or 52 can be used to develop antibodies specific for black bear PTH. These antibodies can be used to quantify black bear PTH, e.g., in an ELISA assay.

PTH receptors on the surface of bone-forming cells are coupled to cyclic adenosine monophosphate (cAMP)-dependent second-messenger signaling pathways inside the cells. These signaling pathways, in turn, lead to increased expression of genes involved in bone formation such as those encoding type I collagen, osteocalcin, and osteopontin. Since the cAMP/ protein kinase A pathway is responsible for the majority of PTH-induced increases in histological and serum indices of bone formation, it follows that an increased cAMP response can lead to greater bone formation. A relatively small number of amino acid substitutions in the sequence of a given PTH protein can stimulate greater cyclic adenosine monophosphate (cAMP) production compared to the native form. For example, ovariectomized rats demonstrated a 25% greater bone formation response to daily 25 μg injections of bovine PTH 1-34 than to rat PTH 1-34, where rat PTH 1-34 has 5 amino acid sequence differences compared to bovine PTH 1-34. Injection of bovine PTH 1-34 results in a 37% greater increase in bone volume fraction during treatment.

Thus, it is likely that the amino acid substitutions in black bear PTH cause it to induce greater cAMP production in bone-forming cells than human PTH. PTH, in general, elicits greater bone formation than human PTH. Since there are differences between black and human PTH sequences, it can be expected that the black bear PTH will induce greater bone formation.

As used herein, “contacting a cell” with a PTH polypeptide includes adding the polypeptide to the culture solution, in the case of in vitro experiments, or administering the polypeptide to a subject using appropriate administration procedures for polypeptide therapeutic agents. “Contacting a cell” also includes introducing into a subject an exogenous polynucleotide that encodes the desired polypeptide in an expression system so as to synthesize and release the polypeptide in the subject. As used herein, “bone-forming cells” includes, but is not limited to, osteoblasts, osteocytes, bone lining cells, chondroblasts, and chondrocytes. Suitably, the bone-forming cell may be a subject.

Bone-forming cells regularly turn over, with most of the cells’ death being due to programmed cell death, or apoptosis. Given this regular rate of turnover, any mechanism that decreases apoptosis of bone-forming cells will lead to an increased number of bone-forming cells which presumably will promote bone growth. Thus, in another embodiment of the present invention, contacting a bone-forming cell with black bear PTH or a functional fragment thereof reduces apoptosis in the bone-forming cell. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising amino acid residues 1-34 or 1-36 of SEQ ID NO: 2. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising SEQ ID NO: 2. Moreover, it is possible that several of the larger C-terminal fragments of endogenous black bear PTH play a role in seasonal bone remodeling processes via binding to CPTHRs (C-terminal PTH receptors). Specifically, C-terminal fragments of bear PTH may antagonize the calcemic effects of PTH 1-84 and 1-34 by preventing osteoclastogenesis and possibly by affecting mature osteoclast activity that would normally occur in response to resorptive stimuli such as disuse (Diweti, P. et al., 2002, Endocrinology 143(1): 171-6). This may help bears to maintain homeostatic calcium levels throughout hibernation. Thus, in another embodiment of the present invention, osteocysts and osteoblasts may be contacted with a polypeptide comprising amino acid residues 11-84 or 7-84 of SEQ ID NO: 2.

The protein Bax promotes apoptosis while the Bel-2 protein protects cells from apoptosis, and a decrease in the expression ratio of Bax to Bel-2 is indicative of a decrease in apoptosis in the particular cell population. Thus, in another embodiment of the present invention, contacting a bone-forming cell with black bear PTH or a functional fragment thereof decreases the ratio of expression levels of Bax protein relative to expression levels of Bel-2 protein in the bone-forming cell. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising amino acid residues 1-34 or 1-36 of SEQ ID NO: 2. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising SEQ ID NO: 2. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising amino acid residues 11-84 or 7-84 of SEQ ID NO: 2.

Example 11 shows that black bear PTH 1-34 decreases the expression ratio of Bax/Bel-2 in cultured cells whereas human PTH 1-34 increases the expression ratio of Bax/Bel-2 (FIG. 7). Thus, black bear PTH 1-34 appears to be more effective at preventing apoptosis than human PTH 1-34. Without being bound by theory, this difference may be the result of the two amino acid differences between human and black bear PTH 1-34. These data suggest that bear PTH is more anabolic than human PTH, since decreased osteoblast apoptosis may contribute to the bone formation response induced by PTH treatment.

Contacting a bone-forming cell with black bear PTH or a functional fragment thereof also increases the expression level of bone matrix protein, a transcriptional activator, or a transcriptional regulator in the bone-forming cell. In another embodiment of the present invention, the transcriptional activator is Runx2. In another embodiment of the present invention, the transcriptional regulator is c-fos. Bone matrix proteins may suitably include osteocalcin, osteopontin, and type 1 collagen. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising amino acid residues 1-34 or 1-36 of SEQ ID NO: 2. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising SEQ ID NO: 2. In another embodiment of the present invention, the
bone-forming cell is contacted with a polypeptide comprising amino acid residues 11-84 or 7-84 of SEQ ID NO: 2.

Exogenous human PTH is used to treat post-menopausal and age-related osteoporosis in humans, but it is not an ideal therapeutic. Only recombinant human PTH 1-34 (LY333334, Eli Lilly, Indianapolis Ind.) is currently approved for clinical use, and only one form of recombinant human PTH 1-84 is under consideration for approval by the U.S. Food and Drug Administration (ALX1-11, NPS Pharmaceuticals, Parsippany, N.J.). Though LY333334 and ALX1-11 can stimulate approximately the same magnitude of bone formation in vivo, their biological actions are not identical. For example, PTH 1-34 down-regulates production of procollagen-1 mRNA, whereas PTH 1-84 does not (Nasu et al., 1998, Endocr J, 45, 229-34). In addition, it has also been determined that the C-terminal portion of human PTH, when cleaved from the mature hormone, has important biological functions such as inhibition of bone resorption.

Long-term usage of either LY333334 or ALX1-11 generates osteosarcoma in rats, but preliminary results indicate that human PTH 1-84 has a lower rate of carcinogenicity than human PTH 1-34, possibly because C-terminal fragments of exogenous human PTH 1-84 (arising from peripheral proteolytic processing) can bind to C-terminal PTH receptors (CPTHRs) and increase osteocyte apoptosis. Thus, though equally anabolic, human PTH 1-84 may be a superior osteoporosis therapy compared to human PTH 1-34. However, human PTH 1-84 cannot completely restore lost bone; it has been suggested that men and women can lose between 20-30% of cortical and cancellous bone due to age-related osteoporosis, but only 8% is recovered using ALX1-11 during its suggested treatment regimen. Therefore, there exists a clinical need for osteoporosis treatments with greater osteogenic capabilities.

In an additional embodiment of the present invention, contacting a bone-forming cell in a subject with black bear PTH or a functional fragment thereof increases bone mineral density, increases bone mass, decreases bone loss or reduces the incidence of bone fracture in the subject. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising amino acid residues 1-34 or 1-36 of SEQ ID NO: 2. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising SEQ ID NO: 2. In another embodiment of the present invention, the bone-forming cell is contacted with a polypeptide comprising amino acid residues 11-84 or 7-84 of SEQ ID NO: 2.

Suitably, contacting a bone-forming cell in a subject with black PTH or a functional fragment thereof increases bone mineral density, increases bone mass, decreases bone loss or reduces the incidence of bone fracture by at least about 5% or at least about 10%. The increase in bone mineral density, increase in bone mass, decrease in bone loss or reduction in the incidence of bone fracture may be at least about 15%, at least about 30%, at least about 50%, at least about 75% or at least about 90%. The increase in bone mineral density, increase in bone mass, decrease in bone loss or reduction in the incidence of bone fracture is determined by measuring the desired characteristic on the same patient before and after treatment by a technique known to one of ordinary skill in the art. For example, bone mineral density can be determined by methods involving taking dual energy x-rays (DEXA) or CT scans of bones in the spinal column, wrist, arm or leg.

The subject may suitably be a mammal, including without limitation human, horse, dog, cat, mouse, bear, bovine, pig, or deer. The subject may have osteoporosis or may be at risk to develop osteoporosis. Risk factors for developing osteoporosis include: personal history of fracture after age 50; current low bone mass; history of fracture in a first-degree relative; being female; being thin and/or having a small frame; advanced age; a family history of osteoporosis; estrogen deficiency as a result of menopause, especially early or surgically induced; abnormal absence of menstrual periods (amenorrhea); anorexia nervosa; low lifetime calcium intake; vitamin D deficiency; use of certain medications (corticosteroids, chemotherapy, anticonvulsants and others); presence of certain chronic medical conditions, such as those that decrease calcium absorption in the gut such as Crohn’s disease; low testosterone levels in men; an inactive lifestyle; current cigarette smoking; excessive use of alcohol; and being Caucasian or Asian; although African Americans and Hispanic Americans are at significant risk as well. Moreover, women can lose up to 20 percent of their bone mass in the five to seven years following menopause, making them more susceptible to osteoporosis.

Black bear PTH or functional fragments thereof are also useful as a preventative (rather than a restorative), or prophylactic, measure to combat disease osteoporosis or to prevent osteoporosis in a subject at risk for developing osteoporosis. Since bears appear to be the only animals that maintain balanced bone remodeling during disuse, black bear PTH or functional fragments thereof are also useful to prevent bone loss during reduced skeletal unloading that occurs, for example, in astronauts during spaceflight and in spinal cord injury patients after injury.

Black bear PTH or functional fragments thereof may be administered in combination with calcium and/or vitamin D. The calcium and/or vitamin D may be administered concurrently with black bear PTH or functional fragment thereof or may be administered before or after black bear PTH or functional fragments thereof. Suitably, "Vitamin D" refers to the entire Vitamin D class of compounds.

Administration of black bear PTH or functional fragments thereof or compositions comprising black bear PTH or functional fragments thereof can be accomplished by any suitable technique. Black bear PTH or functional fragment thereof may be administered by any suitable route including, for example, oral, nasal, rectal, and parenteral routes of administration. As used herein, the term parenteral includes but is not limited to subcutaneous, intradermal, intravenous, intramuscular, intraperitoneal, and intrathecal administration, such as by injection. As is discussed above, administration of a polypeptide includes administration of an exogenous polynucleotide operably connected to a promoter such that the polynucleotide expresses the polypeptide in the subject. Administration of the polypeptide also includes administration of a viral vector comprising a polynucleotide encoding the polypeptide. Suitably, the viral vector is an adenoviral vector.

Black bear PTH or functional fragments thereof, or compositions comprising black bear PTH or functional fragments thereof, can be administered continuously or at discrete time intervals as can be readily determined by a person skilled in the art. An ordinarily skilled clinician can determine a suitable amount of black bear PTH or a functional fragment thereof to be administered to a subject.

The specific effective dose for any particular subject will depend upon a variety of factors, including the disorder being treated and the severity of the disorder; activity of the specific compound employed; the specific composition employed; the age, body weight, general health, sex and diet of the subject; route of administration; the rate of excretion or inactivation of black bear PTH or functional fragments thereof employed;
the duration of the treatment; other pharmaceuticals used in combination or coincidental with black bear PTH or functional fragments thereof and like factors well known in the medical arts. For example, it is well within the level of ordinary skill in the art to start doses at levels lower than those required to achieve the desired effect and to gradually increase the dosage until the desired effect is achieved.

Suitably, the dosage of black bear PTH or functional fragments thereof in one embodiment is in a range of 0.10 µg/kg per day to 40 µg/kg per day. In another embodiment, the dosage is in a range of 5 µg/kg per day to 20 µg/kg per day. In still another embodiment, the dosage is 10 µg/kg per day. In another embodiment, the dosage is in a range of 10 µg/day to 400 µg/day per subject. In yet another embodiment, the dosage is in a range of 20 µg/day to 40 µg/day per subject. In still another embodiment, the dosage is 30 µg/day per subject. In one embodiment the subject is a human. Suitably, the daily dosages in one embodiment are given for one week, in another embodiment for one month, in yet another embodiment for three months, in yet another embodiment for six months, in still another embodiment for one year, in yet another embodiment for one and a half years, in still another embodiment for two years, and in yet another embodiment for three years.

If desired, the effective daily dose may be divided into multiple doses for purposes of administration. Consequently, single dose compositions may contain such amounts or submultiples thereof to make up the daily dose. If desired, a suitable delivery device is loaded with the effective daily dose for more than one day, for example, for seven days, fourteen days, twenty-one days, twenty-eight days or the like, and the delivery device is used to repeatedly administer the desired daily single dose or daily multiple doses for the desired total number of days. As noted, those of ordinary skill in the art will readily optimize effective doses and co-administration regimens as determined by good medical practice and the clinical condition of the individual subject.

Compositions containing black bear PTH or functional fragments thereof useful in the methods of the present invention can be formulated according to known methods for preparing pharmaceutically useful compositions. Formulations are described in detail in a number of sources which are well known and readily available to those skilled in the art. For example, Remington’s Pharmaceutical Science, by E. W. Martin, describes formulations which can be used in the disclosed methods. In general, the compositions will be formulated such that an effective amount of the polypeptide is combined with a suitable carrier in order to facilitate effective administration of the composition.

The compositions used in the present methods can also be in a variety of forms. These include, for example, solid, semi-solid, and liquid dosage forms, such as tablets, pills, powders, liquid solutions or suspension, suppositories, injectable and infusible solutions, and sprays. The form will depend on the intended mode of administration and therapeutic application. The compositions also suitably include conventional pharmaceutically acceptable excipients which are known to those skilled in the art. Examples of excipients include water for injection, ethanol, dimethyl sulfoxide, glycerol, alumina, starch, gelatin, acetic acid, sodium acetate, mannitol, m-cresol, hydrochloric acid and/or sodium hydroxide to adjust the pH of a composition to a suitable value, and equivalent or otherwise suitable carriers and diluents. To provide for the administration of such dosages for the desired application, pharmaceutical compositions will comprise between about 1% and 99%, and suitably between about 1 and 15% by weight of the total of one or more of the polypeptides of the present invention based on the weight of the total composition including the carrier or diluent.

As used herein, an “isolated” nucleic acid molecule, polynucleotide, polypeptide, or the like, as the case may be, refers to a component that is at least partially purified from contaminants (e.g., other species of polynucleotides, polypeptides, or the like) that is found other than in its natural state. An isolated nucleic acid, polynucleotide, or polypeptide may contain less than about 50%, suitably less than about 75%, and most suitably less than about 90%, of the cellular components with which it was originally associated. A polynucleotide amplified using PCR so that it is sufficiently and easily distinguishable (on a gel, for example) from the rest of the cellular components is considered “isolated”. The nucleic acid molecules, polynucleotides, and polypeptides of the invention may be "substantially pure," i.e., having the highest degree of purity that can be achieved using purification techniques known in the art.

As used herein, a “functional fragment” refers to any region or portion of a polypeptide or polynucleotide which is a region or portion of a larger polypeptide or polynucleotide, the region or portion having an activity or function attributable to the larger polypeptide or polynucleotide. For example, a functional fragment of human PTH is the 1-34 region of human PTH.

As used in this specification and the appended claims, the singular forms “a,” “an,” and “the” include plural referents unless the content clearly dictates otherwise. It should also be noted that the term “or” is generally employed in its sense including “and/or” unless the content clearly dictates otherwise.

All publications, patents and patent applications are herein expressly incorporated by reference in their entirety for all purposes to the same extent as if each individual publication or patent application was specifically and individually incorporated by reference. In case of conflict between the present disclosure and the incorporated patents, publications and references, the present disclosure should control.

It also is specifically understood that any numerical range recited herein includes all values from the lower value to the upper value, i.e., all possible combinations of numerical values between the lowest value and the highest value enumerated are to be considered to be expressly stated in this application. For example, if a concentration range is stated as 1% to 50%, it is intended that values such as 2% to 40%, 10% to 30%, or 1% to 3%, etc., are expressly enumerated in this specification. If a concentration range is “at least 5%,” it is intended that all percentage values up to and including 100% are also expressly enumerated. These are only examples of what is specifically intended.

The following Examples are provided to assist in a further understanding of the invention. The particular materials, methods and conditions employed are intended to be illustrative of the invention and are not limiting upon the scope of the invention.

Example 1

Sequencing of Black Bear PTH 1-84

Genomic DNA Extraction

Blood was collected from a captive female black bear and stored at 4° C. Genomic DNA was extracted from the whole blood samples within 2 weeks, using the GenomicPrep Blood DNA Isolation Kit (Amersham Biosciences, Piscataway, N.J.) according to the manufacturer’s instructions.

PCR Cloning and Sequencing

Black bear genomic DNA was used for PCR amplification of PTH, using consensus primers designed based on alignment of eight full-length mammalian PTH sequences available in GenBank including bovine (Bos taurus, A3A30749), cat (Felis catus, Q9C67), dog (Canis familiaris, P52212),...
human (Homo sapiens, NP_000306), macaque (Macaca fascicularis, Q9XT35), mouse (Mus musculus, NP_065648), pig (Sus scrofa, NP_995966), and rat (Rattus norvegicus, NP_058740). PCR amplification was performed using 10-15 ng genomic DNA, 100 pM dNTPs, 0.2 pM each primer, and 1 unit REDTaq (Sigma, St. Louis, Mo.) in 20 μL reaction volume. PCR products were gel-purified using the UltraClean GelSpin Kit (MoBio Carlsbad, Calif.) and cloned into the pCR II vector using the TA cloning kit (Invitrogen, Carlsbad, Calif.). DNA sequencing was performed using the DTCS GelSpin Kit (MoBio Carlsbad, Calif.) and cloned into the pCR II vector using the TA cloning kit (Invitrogen, Carlsbad, Calif.). Sequence analysis was performed using the Dicyclic Quick Start kit and the CEQ8800 Genetic Analysis System (Beckman Coulter, Fullerton, Calif.), following the manufacturer’s instructions.

Sequence Analysis

Nucleotide sequences were searched against the GenBank protein database using BlastX (Altschul et al., 1997; Nucleic Acids Res., 25, 3389-402) to confirm their putative identity as PTH. Multiple sequence alignment was performed by ClustalW version 1.82 (Chenna et al., 2003; Nucleic Acids Res., 31, 3497-500). Phylogenetic analysis was carried out using the neighbor-joining (NJ) method implemented in the Molecular Evolutionary Genetics Analysis (MEGA) package version 3.0 (Kumar et al., 2004; Brief/Bioinform., 5, 150-63), with the pairwise deletion option for handling alignment gaps, and with the Poisson correction model for distance computation.

PTH Cloning and Sequence Analysis

Various primer combinations were used for PCR-based cloning of PTH from black bear genomic DNA. Based on the sequencing results of preliminary clones, a gene-specific sense primer corresponding to the start codon was designed and used along with a degenerate antisense primer containing the stop codon to amplify the entire coding region of PTH. A second antisense primer covering the stop codon was designed to generate a clone for sequence confirmation.

Sequence assembly revealed a precursor PTH protein of 115 amino acids, including a 25 amino acid signal peptide and a 90 amino acid mature peptide. The deduced mature peptide is 84 amino acids, with a calculated molecular weight of 9,471 Daltons and a pI of 8.1. Black bear PTH shares 84-95% sequence similarity with other mammalian PTHs, and is most similar to dog PTH (91% identity, 95% similarity) (FIG. 8). Interestingly, two amino acid residues, 41 and 52 of the mature hormone, are unique to black bear PTH.

Example 2

Levels of Bone Resorption and Formation Markers During Hibernation

Serum Samples

Blood samples were collected from five black bears (Ursus americanus) held in a captive bear research facility. The Virginia Polytechnic Institute and State University Animal Care Committee approved all bear handling protocols (IACUC #96-069-F&WS). The bears were anesthetized with a 2:1 mixture of ketamine (100 mg/ml) : xylazine (100 mg/ml); the dosage was 1 cc of the mixture per 45.5 kg of body weight. Body temperatures were 4° to 6° C. cooler during winter collection, confirming that the bears were in a state of hibernation. No urine or scat was present in the hibernation dens. Stressful behavior was not observed during any of the handling procedures. Blood samples were drawn from the femoral vein while the bears were anesthetized, and the samples were transported to the laboratory in an ice-packed cooler. Immediately on return to the laboratory, the blood was centrifuged to isolate the serum, which was frozen at -20° F.

samples were collected from each bear every 10 days from the first of October through the end of May. Hibernation began in early January and ended in early April. Thus, the collection dates encompassed an active pre-hibernation period, a disuse hibernation period, and an active post-hibernation remobilization period.

Black Bear Osteocalcin Purification and RIA Procedures

Black bear cortical bone was broken into small fragments, defatted with a mixture of 3 parts hexane and 2 parts isopropanol, and lyophilized. The dried bone was ground to a fine powder under liquid nitrogen, and the osteocalcin was solubilized as described by Hauschka et al. (1989, Physiol. Rev., 69, 990-1047). Osteocalcin was purified from the resulting EDTA extract by a modification of the method of Colombo et al. (1993, J. Bone Miner. Res., 8, 733-43). Briefly, the crude EDTA solution was diluted 2-fold and passed over a bulk column containing 10 g Sephracyl C18 particles (Analytech International, Harbor City, Calif.) previously activated with methanol and equilibrated with 0.1% trifluoroacetic acid in water (0.1% TFA). An extensive wash with 0.1% TFA was followed by 30% methanol/0.1% TFA until UV absorbance dropped to baseline. Osteocalcin was eluted with 80% methanol/0.1% TFA. Methanol was evaporated under a stream of air and the remaining solution lyophilized. The resulting dried protein was suspended in 0.05 M Tris buffer, pH 8.0 and applied to a 5 ml Biorad Econo-Q column previously equilibrated with the same buffer. The column was developed with a gradient from 0.1 to 0.6 M NaCl in 0.5 M Tris, pH 8.0. Osteocalcin eluted in a symmetric peak, the last to elute from the column. Identity of this peak as osteocalcin was qualitatively verified by reacting fraction aliquots with diazobenzenesulfonic acid yielding a pink color in those fractions containing osteocalcin, with intensity corresponding to peak height. Both the C18 and the Econo-Q column were new and never exposed to protein from other species. Previous experience with other species suggests the final osteocalcin peak is greater than 99% pure. Concentration of black bear osteocalcin in the final elute was determined by BCA reagents from Pierce Chemical (Rockford, Ill.).

Biochemical Assays

The assay was assayed for PTH, 25-OH D, leptin, IGF-1, and osteocalcin (a bone formation marker) using RIA and ELISA.

Highly purified black bear osteocalcin and black bear serum were assayed by radioimmunoassay. The antibody was guinea-pig anti-rat osteocalcin and tracer was 125I-labeled rat osteocalcin. Dose dilutions of both rat osteocalcin standard (Biomedical Technologies, Inc., Stoughton, Mass.) and purified black bear osteocalcin were included in the assay. Aliquots of 10 μl black bear serum per assay tube were assayed in duplicate, and all samples were assayed at the same time. Duplicates varied by less than 5%.

To observe changes in bone formation and resorption markers during disuse, the mean values of osteocalcin for the 5 black bears were calculated for each time point during the hibernation period. These values were normalized by the maximum osteocalcin value during the hibernation period. Similar calculations were done for measurements of PICP (bone formation marker) and ICTP (bone resorption marker).

The normalized values of the resorption and formation markers were plotted on the same graph to assess the temporal and relative magnitude changes in bone resorption and formation during disuse.

Using serum samples from hibernating bears obtained as described above, ionized calcium concentration was measured with an ion-selective electrode (Bayer Rapidlab 865, Leverkusen, Germany).
Hibernation

Mean values are given in bold, standard deviations in parentheses, and sample sizes in brackets. For a given metabolite, values with the same superscript are not significantly different (p < 0.05). 25-OH D did not show significant seasonal differences.
encompassed a pre-hibernation active period, a hibernation disuse period, and a post-hibernation remodeling period. MC-3T3 osteoblastic cells were cultured for 24 hours in media containing 10% bear serum, after which total RNA was isolated using a BioRad AquaPure RNA Isolation Kit (#732-6370, Bio-Rad Laboratories, Hercules, Calif.). To generate cDNA, reverse transcription was performed using SuperScript II reverse transcriptase (Invitrogen, Carlsbad, Calif.), and 0.5 μg Oligo(dT) 12-18 primer at 42°C for 20 minutes, 50°C for 10 minutes and 42°C for 1 hour in a gradient thermocycler (Mastercycler gradient, Eppendorf, Westbury, N.Y.). Primers for the pro-apoptotic protein Bax and the anti-apoptotic protein Bel-2 were designed using PrimerQuest software (Integrated DNA Technologies, Coralville, Iowa) and the NCBI gene bank sequences. Semi-quantitative PCR was performed using RedTaq and a protocol consisting of 94°C for 30 seconds, 69°C for 30 sec and 72°C for 1 minute, and a final extension at 72°C for 5 minutes. Band intensity was quantified using the ImageJ software package (National Institutes of Health, Bethesda, Md.) and normalized to the expression of three housekeeping genes (Gapdh, β-actin, cyclophilin).

ANOVA with Fisher’s Protected Least Significant Difference (PLSD) post-hoc test was used to compare the ratio of Bax to Bel-2 for the three seasons (pre-hibernation, hibernation, post-hibernation). Though it did not achieve statistical significance (p=0.300), the Bax/Bel-2 ratio decreased by approximately 42% during hibernation relative to post-hibernation. The lack of statistical significance was likely related to the small sample size (n=2 for each season). These data suggest that serum from hibernating bears contains a biological molecule that decreases osteoblast apoptosis. Since endogenous PTH and the bone formation marker osteocalcin both increase during hibernation (Donahue et al., 2006; J. Exp. Biol. 209, 1630-8), it is possible that endogenous bear PTH causes a decrease in osteoblast apoptosis during hibernation, which in turn increases bone formation.

Example 5

Comparison of Effects of Black Bear vs. Human PTH 1-84 or Subfragments Thereof on cAMP in Bone Cell Lines

Full-length recombinant black bear PTH (residues 1-84) is produced and its effects on levels of cyclic adenosine monophosphate (cAMP) concentration in bone cell lines (MC-3T3 osteoblastic cells and MLO-Y4 osteocytic cells) are investigated and compared to results obtained using recombinant human PTH 1-84. Equivalent experiments are conducted using subfragments of black bear and human PTH, the subfragments including amino acid residues 1-34, 1-36, 7-84, 11-84, and 41-52 of the full-length (1-84) mature protein. For some experiments, black bear and human PTH polypeptides are synthesized with solid-phase methods.

To determine the effect of various forms of recombinant black bear and human PTH polypeptides on cAMP levels in bone-forming cells, the cultured bone cells (MC-3T3 and MLO-Y4) are contacted for 10 or 30 minutes with human or black bear PTH full-length (i.e. amino acid residues 1-84) polypeptide or one of the above-listed subfragments. After the cell is contacted with the PTH polypeptide, cAMP concentration in the cell is measured using a competitive binding assay as described further below.

For all of the experiments using recombinant polypeptides, the lyophilized peptides are reconstituted to 100 μM stock concentrations in 1 mM acetic acid, and diluted to 10 μM working stock concentrations before use.

Cell Culture

MC-3T3 subclone 14 cells (ATCC, CRL-2594) and MLO-Y4 cells (obtained from L. F. Bonewald, University of Missouri, Kansas City, Mo.) are maintained in alpha-minimum essential media, 1% penicillin/streptomycin, and 10% serum (MC-3T3, 10% fetal bovine serum (FBS), MLO-Y4; 5% FBS and 5% bovine calf serum), at 37°C in 5% CO2. All procedures described herein are repeated with independent cell cultures such that n=6 for all treatment combinations in each assay.

Effects of PTH Treatment on Intracellular cAMP Activity

MC-3T3 and MLO-Y4 cells are seeded at appropriate densities (MC-3T3: 50,000 cells/cm², MLO-Y4 15,000 cells/cm²) in 6-well plates. Cells are cultured overnight to reach optimal confluence. The culture media is then aspirated and replaced with media containing either 10% serum+vehicle (1 mM acetic acid) or 10% serum+100 nM PTH (human or bear 1-84, or a subfragment thereof. Cells are cultured under these conditions for 10 or 30 minutes (Carter, P. H. et al., 1999, J. Biol. Chem. 274 (45), 31955-60; Chen, X. et al., 2002, Am. J. Physiol. Cell Physiol. 283 (5), C1432-40; Schiller, P. C. et al., 1999, J. Bone Miner. Res. 14 (9), 1504-12). Following culture, the cells are trypsinized, centrifuged, and resuspended in lysis buffer. The suspension is incubated for 10 minutes and centrifuged to separate cellular debris. The supernatant from the cell lysate (following a 2-fold dilution) is assayed for cAMP concentration using a competitive binding assay (Cyclic AMP Assay #KGE002, R&D Systems, Minneapolis, Minn.).

With each of the polypeptides tested, there is an increase in cellular cAMP levels in response to the black bear PTH-based polypeptide.

Example 6

Comparison of Effects of Black Bear vs. Human PTH 1-84 or Subfragments Thereof on Apoptosis in Bone Cell Lines

Full-length recombinant black bear PTH (residues 1-84) is produced and its effects on apoptosis in bone cell lines (MC-3T3 osteoblastic cells and MLO-Y4 osteocytic cells) are investigated and compared to results obtained using recombinant human PTH 1-84. Equivalent experiments are conducted using subfragments of black bear and human PTH, the subfragments including amino acid residues 1-34, 1-36, 7-84, 11-84, and 41-52 of the full-length (1-84) mature protein. For some experiments, black bear and human PTH polypeptides are synthesized with solid-phase methods.

To determine the relative ability of black bear and human PTH to prevent osteoblast and osteocyte apoptosis (under pro-apoptotic conditions), cells are incubated with human or black bear PTH 1-84, or one of the subfragments listed above, for one hour. Afterwards, cells are treated for 6 hours with dexamethasone to induce apoptosis. Apoptosis is quantified with an ELISA, as described further below.

For all of the experiments using recombinant polypeptides, the lyophilized peptides are reconstituted to 100 μM stock concentrations in 1 mM acetic acid, and diluted to 10 μM working stock concentrations before use.

Additional experiments are performed with MC-3T3 cells using either 0.1% or 10% FBS. Additional experiments with less (0.1%) than the normal (10%) amount of FBS are run and the results are analyzed to determine whether there is a significantly different response between experiments that are
run with normal or lower levels of serum. In the experiments reported in this Example, the results are not affected by the amount of FBS that is used. Apoptosis protection studies show that each of the polypeptides tested reduces or prevents apoptosis in MC-3T3 cells.

Cell Culture

MC-3T3 subclone 14 cells (ATCC, CRL-2594) and MLO-Y4 cells (obtained from L. F. Bonewald, University of Missouri, Kansas City, Mo.) are maintained in alpha-minimum essential media, 1% penicillin/streptomycin, and 10% serum (MC-3T3: 10% fetal bovine serum (FBS), MLO-Y4: 5% FBS and 5% bovine calf serum), at 37°C in 5% CO₂. All procedures described herein are repeated with independent cell cultures such that n=6 for all treatment combinations in each assay.

Effects of PTH Treatment on Apoptosis

MC-3T3 cells are seeded at 50,000 cells/cm², and MLO-Y4 cells are seeded at 15,000 cells/cm² in 6-well plates and cultured overnight to reach optimal confluence. The culture media is aspirated and replaced with media containing either 10% serum+vehicle (1 mM acetic acid) or 10% serum+100 nM PTH (human or bear 1-84, or a subfragment thereof). After a one-hour incubation (Jilka et al., 1999; J. Clin. Invest., 104, 439-46), 10μM dexamethasone or its vehicle (DMSO) is added to each well and cells are incubated for 6 hours (Belldio, T., et al., 2003, J. Biol. Chem. 278(50), 50259-72; Jilka et al., 1999, J. Clin. Invest., 104, 439-46). The PTH polypeptide or vehicle is left in situ during apoptosis induction because the suppression of apoptosis by PTH is self-limiting (Belldio et al., 2003). After 6 hours, cells are trypsinized, centrifuged, resuspended, and counted using a hemocytometer. 50,000 cells are removed from the suspension and placed into lysis buffer. The lysate supernatant (following centrifugation) is removed for analysis and stored at −20°C.

Apoptosis is quantified from the lysate supernatant with an ELISA (Cell Death Detection ELISA, #1544675, Roche Applied Science, Indianapolis, Ind.). This assay detects mono- and oligonucleosomes from fragmented cellular DNA in the cytoplasmic fraction of cell lysates, and therefore provides a good measure of the early and middle stages of apoptosis. Briefly, samples are diluted in buffer solution and resuspended, and counted using a hemocytometer. 50,000 nM PTF1 (human or bear 1-84, or a subfragment thereof).

Effects of PTH Treatment on Gene Expression

MC-3T3 cells are seeded at a density of 50,000 cells/cm², and MLO-Y4 cells are seeded at a density of 15,000 cells/cm² in 6-well plates and cultured overnight to reach optimal confluence. The culture media are aspirated and replaced with media containing either 10% serum+vehicle (1 mM acetic acid) or 10% serum+100 nM PTH (human or bear 1-84, or a subfragment as listed above). Cells are cultured under these conditions for 1 or 3 hours; these time points correspond with PTH-induced upregulation of c-fos and osteocalcin (Jiang et al., 2004, J. Biol. Chem., 279, 5329-37; Chen et al., 2002). Total RNA is isolated using the SV Total RNA Isolation System (Promega, Madison, Wis.).

Reverse transcription to generate cDNA is performed using Superscript II reverse transcriptase (Invitrogen, Carlsbad, Calif.), and 0.5 μg Oligo(dT) 12-18 primer at 42°C for 20 minutes, 50°C for 10 minutes and 42°C for 1 hour in a gradient thermocycler (Mastereycler gradient, Eppendorf, Westbury, N.Y.). Primers for all genes of interest (ostecalcin, osteopontin, type 1 collagen, c-fos, Runx2, Bax, Bcl-2, SOST) and housekeeping genes (Gapdh, β-actin, cyclophilin) are designed using PrimerQuest software (Integrated DNA Technologies, Coralville, Iowa) and the NCBI gene bank sequences, and the PCR conditions are optimized using RNA from MC-3T3 and MLO-Y4 cells. Real-time PCR is performed using the Mx3000P real-time PCR system (Stratagene, La Jolla, Calif.). The protocol involves a hot start at 95°C for 10 minutes followed by 40 cycles of 95°C for 30 seconds (denaturation), 60°C for 1 minute (annealing) and 72°C for 1 minute (extension). The exception to this protocol is for c-fos, which has an annealing temperature of 66°C. Each 25 μl reaction contains 1× Absolute™ qPCR SYBR® green mix (ABgene, Rochester, N.Y.), 0.1 μM forward and reverse primer, and 2.5 ng total RNA equivalent cDNA template. Gene expression is determined using the relative standard curve method normalized to the geometric mean of the
until the end of May. Hibernation begins in early January and
which is then frozen at -20° C. Blood samples are collected
from at least 3 different female black bears (Ursus americanus pallas) held in the Virginia Tech Center for Bear Research between 2004 and 2005. Serum from additional black bears is collected in subsequent years. The Virginia Polytechnic Institute and State University Animal Care Committee approved all bear handling protocols (#98-069-F&WS). The bears are anesthetized with a 2:1 mixture of ketamine (100-mg/ml):xylazine (100-mg/ml); the dosage is 1 cc of the mixture per 45.5 kg of body mass. Blood samples are drawn from the femoral vein while the bears are anesthetized, and the samples are transported to the laboratory in an ice-packed cooler. Immediately on return to the laboratory, the blood is centrifuged to isolate the serum, which is then frozen at -20° C. Blood samples are collected from each bear every 10 days from the beginning of October until the end of May. Hibernation begins in early January and ends in early April. Thus, the collection dates encompass an active pre-hibernation period, a disuse hibernation period, and an active post-hibernation remobilization period.

Aliquots of 10 µl of bear serum are assayed in duplicate for osteocalcin concentration by radioimmunoassay (Patterson-Alten et al., 1982; Anal. Biochem., 120, 1-7). This assay has previously been validated for bears (Donahue et al., 2006; J. Exp. Biol., 209, 1630-8). The antibody is guinea-pig anti-rat osteocalcin and tracer is [125I]-labeled rat osteocalcin. Aliquots of 100 µl of bear serum are assayed in duplicate for PTH concentration (Donahue et al., 2006; J. Exp. Biol., 209, 1630-8) with an ELISA (Porcine Intact PTH ELISA Kit, #60-3305, Immutopics, Inc., San Clemente, Calif.). This assay binds the 39-84 region of PTH, and requires the 13-34 region of PTH to calorigmatically report PTH concentration. Thus, it provides a good measure of intact (1-84) PTH concentration as well as C-terminal subfragments 7-84 and 11-84. This ELISA has been shown to cross-react with bear PTH (Donahue et al., 2006; J. Exp. Biol., 209, 1630-8), and has 100% cross-reactivity with human PTH. To validate this assay for black bears, samples of culture media containing 10 nM recombinant bear or human PTH 1-84 are assayed in duplicate. The known concentration of the PTH samples is compared to the measured concentration determined from the assay’s standard curve. Any potential difference in cross-reactivity determined from these samples is used as a correction for endogenous black bear PTH concentration in the black bear serum samples.

The procedures described above for recombinant black bear PTH apoptosis and gene expression cell culture experiments with cultured bone-type cells are repeated, substituting the 100 nM recombinant PTH-containing media with culture media containing 10% black bear serum (from pre-hibernation, hibernation, or post-hibernation periods). The serum volumes are calculated following the PTH ELISA described above.

Serum from the hibernation and post-hibernation seasons causes a greater prevention of apoptosis compared to pre-hibernation serum, because PTH is higher during hibernation and post-hibernation than in pre-hibernation serum. Endogenous serum PTH concentrations are inversely related to apoptosis levels, in that higher serum PTH levels correspond to lower rates of apoptosis, i.e. serum PTH concentrations are negatively correlated with apoptosis levels.

Example 9

In Vivo Testing of Bear PTH

Black bear PTH, either full-length (1-84) or one of several functional subfragments thereof (1-34; 1-36; 7-84; 11-84; 41-52), are tested in vivo for anabolic stimulation of bone cells compared to an equivalent human PTH or subfragment. Each of the PTH polypeptides is synthesized and suspended in a pharmaceutically-appropriate carrier for subcutaneous injection. Full-length PTH or a functional fragment thereof, from either black bear or human, is administered to mice at a dose of 40 µg/kg body weight daily for 7 weeks. Black bear PTH or a functional fragments thereof cause greater increases in bone strength, mass, and mineral content than the equivalent human PTH polypeptide.

Example 10

Use of Bear PTH as Prophylactic Agent to Reduce or Prevent Bone Loss

Osteoporosis is induced in mice by hindlimb suspension (a disuse model of osteoporosis) and by ovariectomy (a post-menopausal model of osteoporosis). After the hindlimb suspension begins or the ovariectomy is completed, the mice is given regular doses of black bear PTH or a functional fragment thereof. The mice treated with black bear PTH or functional fragments thereof show less bone loss than untreated mice.

Example 11

Bear and Human PTH 1-34 Both Upregulate Gene Expression of Osteocalcin, but Only Bear PTH 1-34 Decreases the Expression Ratio of Bax/Bcl-2

MC3T3 cells were incubated in vehicle or 100 nM synthetic bear or human PTH 1-34 for 3 or 6 hours (n=2 or 4). Total RNA was isolated, and cDNA was generated with reverse transcription. Primers for the bone matrix proteins type I collagen and osteocalcin, the anti-apoptotic protein Bax, the anti-apoptotic protein Bcl-2, and the housekeeping genes Gapdh, β-actin, and cyclophilin were designed using PrimerQuest software (Integrated DNA Technologies, Coralville, Iowa). Real-time PCR was performed using the Mx3000P real-time PCR system (Stratagene, LaJolla, Calif.). All samples were measured in duplicate. Gene expression was determined using the relative standard curve method normalized to the geometric mean of the three housekeeping genes (Gapdh, β-actin, and cyclophilin). Apoptosis-related genes were analyzed as the expression ratio of Bax/Bcl-2, since a decrease in this ratio is associated with decreased apoptosis in vitro.

Culture in human or bear PTH 1-34 for 6 hours did not affect expression of type I collagen but substantially upregulated the expression of osteocalcin compared to the vehicle control (FIG. 6). There were no significant differences between human and bear PTH (p>0.09).

Culture in bear PTH 1-34 for 3 hours decreased the expression ratio of Bax/Bcl-2, suggesting decreased apoptosis, but culture in human PTH 1-34 for 3 hours increased the ratio, suggesting increased apoptosis (FIG. 7). The difference between bear and human PTH was statistically significant (p<0.047).

What is claimed is:

1. A method of increasing cAMP levels in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide increases cAMP levels in the bone-forming cell, and wherein the bone-forming cell is in a human subject.

2. The method of claim 1, wherein the polypeptide comprises amino acid residues 1-36 of SEQ ID NO: 2.

3. The method of claim 1, wherein the polypeptide comprises SEQ ID NO: 2.

4. A method of reducing apoptosis in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide reduces apoptosis in the bone-forming cell, and wherein the bone-forming cell is in a human subject.

5. The method of claim 4, wherein the polypeptide comprises amino acid residues 1-36 of SEQ ID NO: 2.

6. The method of claim 4, wherein the polypeptide comprises SEQ ID NO: 2.

7. A method of decreasing the ratio of expression levels of Bax protein to Bcl-2 protein in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide decreases the ratio of expression levels of Bax protein to Bcl-2 protein in the bone-forming cell, and wherein the bone-forming cell is in a human subject.

8. The method of claim 7, wherein the polypeptide comprises amino acid residues 1-36 of SEQ ID NO: 2.

9. The method of claim 7, wherein the polypeptide comprises SEQ ID NO: 2.

10. A method of increasing the expression level of one or more of a bone matrix protein, a transcriptional activator, or a transcriptional regulator in a bone-forming cell comprising contacting the bone-forming cell with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide increases the expression level of the bone matrix protein, transcriptional activator, or transcriptional regulator in the bone-forming cell, and wherein the bone-forming cell is in a human subject.

11. The method of claim 10, wherein polypeptide comprises amino acid residues 1-36 of SEQ ID NO: 2.

12. The method of claim 10, wherein the polypeptide comprises SEQ ID NO: 2.
13. A method of enhancing bone mineral density, increasing bone mass, decreasing bone loss, or reducing the incidence of bone fractures, or any combination thereof, in a human subject, comprising contacting a bone-forming cell in the human subject with an effective amount of a polypeptide comprising amino acid residues 1-34 of SEQ ID NO: 2, wherein contacting the bone-forming cell with the polypeptide enhances bone mineral density, increases bone mass, decreases bone loss, or reduces the incidence of bone fractures in the human subject.

14. The method of claim 13, wherein the human subject is a post-menopausal female human afflicted with osteoporosis.

15. The method of claim 13 further comprising administering vitamin D and calcium to the human subject.

16. The method of claim 13, wherein the polypeptide comprises amino acid residues 1-36 of SEQ ID NO: 2.

17. The method of claim 13, wherein the polypeptide comprises SEQ ID NO: 2.

18. A method of enhancing bone mineral density, increasing bone mass, decreasing bone loss, or reducing the incidence of bone fractures, or any combination thereof, in a human subject, comprising contacting a bone-forming cell in the human subject with an effective amount of a polypeptide comprising bear parathyroid hormone or a functional fragment thereof, wherein contacting the bone-forming cell with the polypeptide enhances bone mineral density, increases bone mass, decreases bone loss, or reduces the incidence of bone fractures in the human subject.
